#### Introduction

- Does a higher level of educational attainment generally increase personal earnings income across different states?
- Do personal earnings increase with an individual's health?
- Do older individuals generally earn more money than younger individuals?

Given the rise in inflation and cost of living, exploring the relationships connected to personal earnings across different states is fundamental to understanding how factors like education, health status, and age, influence income disparities at a regional level. This inquiry is grounded in the longstanding debate within economic and social research regarding the return on investment in education, health, and wellness. By analyzing U.S. Census data, we can gain detailed insights into the nation's political and economic structures, examining how local economies, policies, and opportunities influence each community. This analysis underscores the importance of ensuring that every community receives its fair share of resources, tailored to its unique needs. (Bureau, 2021). In addition, it is crucial to the political sphere with its use in redrawing a multitude of political boundaries to ensure each district contains roughly equal numbers of people thereby addressing funding disparities (Mather & Scommegna, 2019).

The dataset was merged on a state basis, focusing on individuals 18 and older to better represent the adult population. It includes averages of education level, gender, work expenses, and age from the ASEC survey, combined with unemployment rates from the Bureau of Labor Statistics and sales tax rates from the Tax Foundation at the state level.

## Methods and Analysis

Before the model building process began, the data was first subsetted to exclude the observation corresponding to the District of Columbia. Exploratory data analysis revealed that it was the sole territory with the level of "Bachelor's Degree" as the response to the variable, "H\_ED," or highest educational attainment. As this variable was believed to be a significant predictor in the model, this observation was excluded from the model to prevent skew or extrapolation. Following the removal of this observation, a histogram of the response, pearsonal earnings, appeared to be unimodal with moderate right skew and minimal outliers present.

The first stage of the model building process then began: fitting the model with quantitative predictors. Scatterplots of each quantitative variable with the response showed varying degrees of association. Moderate to strong relationships with the response existed with four variables: unemployment rate, tax rate, work expenses, and urban percentage. These four variables were used to build a model, resulting in a globally significant model. The model was reduced via the performance of individual t-tests to include only the two most significant quantitative predictors, urban percentage and work expenses.

Next, qualitative predictors were added to the model. The examination of boxplots of the three qualitative variable with the response suggested that alternative levels of sex does not significantly impact earnings; the median personal earnings of states with a predominantly female workforce is approximately equivalent to those with a predominantly male workforce. However, differing levels of education and health status suggested significant different responses to personal earnings, indicated by non-overlapping interquartile ranges of differing levels for these variables. Therefore, these two quantitative variables, highest education level and health status were added to the model in the second stage of the model building process. The proposed model demonstrated significance by the global f-test. Individual t-tests were then performed to build a model with two predictors: urban percentage and highest educational attainment. The quantitative work expenses predictor became insignificant upon that addition of qualitative predictors, and health status did not demonstrate individual significance.

No interactions were believed to be influencing the model; the only base level variables that remained were urban percentage and highest educational attainment.

ANALYSIS: - Multiple linear regression logistic regression - Include required analysis steps
- Include the "added techniques" that you selected - Assessing the model. - Selecting a
final "best" model. - NOTE: Your analysis should follow the appropriate order on your
poster with a logical flow

Model building with significance testing (should be supported by EDA and/or variable screening) • Identify and check for multicollinearity • Residual analysis (assumptions + extreme observations) Make necessary adjustments as you see fit. If you are attempting to correct a violation, you only need to try up to three corrections, if the first doesn't work. Include plots or output as needed. • Final model selected should be assessed. It may not be great, but you will explain that in conclusion • Include at least ONE additional techniques from the list to add to your analysis: Weighted least squares (Ch 9.4), External Model validation (Ch 5.11), box -cox transformation (supplemental), or another technique or aspect of MLR you learned on your own. • NOTE: if you have a unique situation with your data-

discuss your analysis plan with Prof Varanyak

### Results

The statistical interpretation of the final model. This should be in statistical terms and overall interpreting and assessing the statistical usefulness of the model with the appropriate metrics. There should be no R output (that will go in the appendix). However, you will include your final model.

 $PEARNVAL = 47408.52 + 191.95URB\_PER - 7017.40H\_ED vocational associates$ 

This model is statistically significant with a p-value < 0.0001 and an adjusted r-squared value of 0.56, indicating that this model accounts for 56% of the variation in the data. Additionally, The  $R^2$  value of 0.5792 suggests that approximately 57.92% of the variance in personal earnings can be explained by urban percentile and higher education.

## Conclusions

In our final model, urban percentile and level of higher education are the most significant variables for predicting personal earnings by state. Our model shows that increase in urban percentile (URB\_PER) leads to higher personal earnings whereas possession of a higher education vocational associate's degree (H\_EDvassoc) results in lower personal earnings in the United States.

When estimating the average personal earnings of Virginia given an URB\_PER of 75.5 and H\_EDVassoc of 0, the model predicted that the personal earnings would be \$61,900.74; the actual earnings were \$71,818.63. The prediction was off by \$9,917.89, a percent error of 13.8%.

While urban environment and educational attainment do influence personal income, they may not be the most robust predictors. Additional variables or more complex models could be necessary to capture the full dynamics of affecting personal income and increase its accuracy. Further research could include other variables not analyzed by our data, such as family size or occupation. Additionally, since we were using 2020 Census data, that could cause a skew towards high unemployment and decrease in personal earnings due to the state of the economy during the global pandemic. Thus, increasing our dataset to beyond 2020 can be beneficial at creating more observations. We could also modify existing variables by treating gender as a continuous proprotion instead of a binomial variable. In all, this model

is a good starting point for understanding the relationship between urban environment, educational attainment, and personal earnings, but further research is needed to create a stronger model.

# Appendix A: Data Dictionary

| Reference                 | Variable  |  |  |  |  |  |
|---------------------------|-----------|--|--|--|--|--|
| Name                      | Name      | Description  |  |  |  |  |
| State by FIPS<br>Code     | STATEFIPS | A qualitative measure that identifies the U.S. state (or D.C.) corresponding to the observation by a standardized numeric code. The 51 possible levels are discrete, ranging from 1-56, omitting 3, 7, 14, 43, and 52.                     |  |  |  |  |
| State                     | State     | A qualitative measure that identifies the state corresponding to the observation. The 51 possible levels are names of the 50 U.S. states and the District of Columbia.   |  |  |  |  |
| Educational<br>Attainment | H_ED      | A qualitative measure that identifies the average of highest education among adult residents of a given state. The three possible levels include a Vocational Associate's Degree, an Academic Associate's Degree, and a Bachelor's Degree. |  |  |  |  |
| Majority Sex              | SEX       | A qualitative measure that identifies the predominant sex among a state's adult residents. Two possible levels, male and female, indicate if the adult population of a state is predominately male or female.                              |  |  |  |  |
| Health Status             | HEA       | A qualitative measure that reports the average health status of a state's residents. Two levels, very good health and good health indicate the average health status of a state's residents.   |  |  |  |  |
| Personal<br>Earnings      | PEARNVAL  | A continuous quantitative measure that reports the average personal earnings of a state's residents, reported in U.S. Dollars. Possible values within the data range from \$45096.53 to \$95387.40.  |  |  |  |  |
| Age                       | AGE       | A continuous quantitative measure that reports the average age of a state's adult residents in years. Values range from 40.83460 to 46.39759.  |  |  |  |  |

| Reference      | Variable   |   |  |  |  |  |
|----------------|------------|---|--|--|--|--|
| Name           | Name       | Description   |  |  |  |  |
| Unemployment   | UNEMP_RATE | A continuous quantitative measure of a state's                      |  |  |  |  |
| Rate           |            | unemployment rate from 2020. Unemployment rate is                   |  |  |  |  |
|                |            | reported as a percentage; the range of possible values              |  |  |  |  |
|                |            | within the data is from $4.2\%$ to $13.5\%$ .                       |  |  |  |  |
| Sales Tax Rate | TAX_RTE    | A continuous quantitative measure of a state's sales                |  |  |  |  |
|                |            | tax. Sales Tax Rate is reported as a numerical figure;              |  |  |  |  |
|                |            | the range of possible values within the data is from                |  |  |  |  |
|                |            | $0.0\%~(0\%~{\rm sales~tax})$ to $7.25\%~(7.25\%~{\rm sales~tax}).$ |  |  |  |  |
| Percentage of  | URB_PER    | A continuous quantitative measure of a state's                      |  |  |  |  |
| Urban          |            | proportion of urban residents to nonurban residents.                |  |  |  |  |
| Residents      |            | This variable is reported as a percentage; the range of             |  |  |  |  |
|                |            | possible values within the data is from $38.7\%$ to                 |  |  |  |  |
|                |            | 100.0%.   |  |  |  |  |
| Work Expenses  | WRK_SPND   | A continuous quantitative measure that identifies the               |  |  |  |  |
|                |            | average amount of money spent on work-related                       |  |  |  |  |
|                |            | expenses among residents of a state, reported in U.S.               |  |  |  |  |
|                |            | Dollars. Possible values in the data range from                     |  |  |  |  |
|                |            | \$1101.676 to \$1463.411.   |  |  |  |  |
